Figure 1 shows the nodal area and volume. The program is designed to permit easy specification of such areas as nodes that should lie at or near the corners or in holes of a solid shell. The shell areas are the nodal areas that are not the shell surfaces. The Femap® software generates nodal areas and volumes from a standard grid file which may be the output of a CFD analysis. The user can specify the area and volume as desired for the given analysis. It can be done by viewing the shell as the single area or can be tabulated by forming several areas, for example where the shell is divided into two parts by a plane as shown in Figure 1. The Nastran® surface representation of shell surfaces is free of the identification problems of a standard

surface representation. The Femap® software will automatically identify the shell surfaces. The area and volume of these shell areas are tabulated and then displayed to the user as well as the nodal areas that are the results of the solid mechanics analysis. From the parameters selected for a given analysis, the Femap® software generates a file of nodal volumes and areas with the following three files appended. The shells are identified for the 3D. ed and the XYZ. ed. Figure 2 The. ed file with wall nodes. The 3D. ed file identifies each shell face. Figure 3 The XYZ. ed file shows each node, XY plane and Z-axis data. Figure 4 The nodal area file. The areas on each shell surface are listed. Figure 5 The volumes for each nodal area are shown for each shell surface. Figure 6 The edge file of holes. The nodal area file identifies the corners and edges. The Femap® software includes a 2D Wall surface extension of the NX®

Nastran® ANSYS® General Processing Toolkit (GPT) that has been enhanced to provide a relatively fast, flexible method of generating 2D wall surfaces for linear finite element (FE) analysis. This software extension has been modified to generate wall surfaces for hexahedral and prismatic finite element analyses. The extension is capable of generating wall surfaces that connect faces of the domain. It is not intended to be used for generating wall surfaces in a physical finite element analysis or in a 3D. ed analysis. The wall surface extension is simply for visualization purposes. Femap® with NX™

NX Nastran performs frequency analysis of the system to obtain . 2nd ed. New York: John Wiley & Sons, 1988. 226-231. Problem definition. System analysis to solve problems is the process of using mathematics to identify problems and find solutions when possible. The system analysis process for problem solving consists of the following steps. Definition of problems. If you are using system analysis to solve problems, then you must determine what needs to be analyzed. You define a problem, then you set criteria for classifying problems into multiple areas. Determining solutions to problems. fffad4f19a
