Pneumatic distending pressure at the orifice of the esophageal tracheal Y-piece and spontaneous breathing during pediatric anesthesia. The authors studied the relationship between the degree of manual positive pressure used to inflate the artificial airway at the esophageal-tracheal Y-piece and the extent of spontaneous ventilation during anesthesia. They also assessed whether there was a relationship between the percentage of inspired oxygen and the degree of spontaneous ventilation. Forty healthy children, aged 3-12 yr, undergoing general anesthesia with a laryngeal mask airway were randomly assigned to four groups: group (I) (n = 10), 10 cm H₂O; group (II) (n = 10), 20 cm H₂O; group (III) (n = 10), 30 cm H₂O; and group (IV) (n = 10), 40 cm H₂O. Anesthesia was induced and maintained with sevoflurane in oxygen, without volume-controlled ventilation (VCV) using a face mask. The continuous non-invasive observation of the stethoscope was used to determine the presence and amount of spontaneous ventilation. All groups showed a significantly greater incidence of spontaneous ventilation when manual pressure was increased (groups II and III) than when the manual pressure was 10 cm H₂O (group I) (p Actions Here's what we know about the deadly power outage Posted: 8:23 PM, Jan 02, 2018 Updated:2018-01-03 06:24:12Z
